19 **1 The New Realities of Living in a Big Data Society**

20 To realize the promise and prospects of a Big Data society and avoid its security and confiden-
21 tiality perils, institutions are updating operational frameworks governing business, legal, and

22 technical dimensions of their internal organization and interactions with the outside world. In
23 this chapter we explore the emergence of the Big Data society, outline ways to support it in the
24 context of institutional controls within the framework of the New Deal on Data, and describe
25 future directions for research and development.

26 The control points traditionally relied upon as part of corporate governance, management
27 oversight, legal compliance, and enterprise architecture must evolve and expand to match oper-
28 ational frameworks for Big Data. An operational framework used for a Big Data driven organi-
29 zation requires a balanced set of institutional controls. These controls must support and reflect
30 greater user control over personal data, as well as large scale interoperability for data sharing be-
31 tween and among institutions. Core capabilities of these controls include responsive rule-based
32 systems governance and fine-grained authorizations for distributed rights management.

33 Sustaining a healthy, safe, and efficient society is a scientific and engineering challenge dating
34 back to the 1800s when the Industrial Revolution spurred rapid urban growth, thereby creating
35 huge social and environmental problems. The remedy then was to build centralized networks
36 that delivered clean water and safe food, enabled commerce, removed waste, provided energy,
37 facilitated transportation, and offered access to centralized health care, police, and educational
38 services. These networks formed the backbone of society as we know it today.

39 These century-old solutions are, however, becoming increasingly obsolete and inefficient. We
40 have cities jammed with traffic, world-wide outbreaks of disease that are seemingly unstoppable,
41 and political institutions that are deadlocked and unable to act. We face the challenges of global
42 warming, uncertain energy, water, and food supplies, and a rising population and urbanization
43 that will add 350 million people to the urban population by 2025 in China alone [15].

44 It does not have to be this way. We can have cities that are energy efficient, have secure food
45 and water supplies, are protected from pandemics, and enjoy much better governance. To reach
46 these goals, however, we need to radically rethink our approach. Rather than static fixed systems
47 separated by function — water, food, waste, transport, education, energy — we must consider
48 them as dynamic, data-driven networks. Instead of focusing only on access and distribution,

49 we need the networked and self-regulating systems, driven by the needs and preferences of the
50 citizens.

51 Sustainable future society depends on our new technologies being used to create a *nervous*
52 *system* maintaining the stability of government, energy, and public health systems around the
53 globe. The digital feedback technologies are today capable of creating a level of dynamic re-
54 sponsiveness that our larger, more complicated modern society requires. We must reinvent the
55 systems of societies within a control framework: sensing the situation, combining these observa-
56 tions with models of demand and dynamic reaction, and finally using the resulting predictions
57 to tune the system to match the demands.

58 The engine driving this nervous system is Big Data: the newly ubiquitous digital data, now
59 available about all aspects of human life. We can analyze patterns of human experience and
60 ideas exchange within the *digital breadcrumbs* that we all leave behind as we move through
61 the world: call records, credit card transactions, GPS location fixes, among others [25]. By
62 recording our choices, these data tell the story of our lives. And this may be very different from
63 what we decide to put on Facebook or Twitter; our postings there are what we choose to tell
64 people, edited according to the standards of the day and filtered to match the persona we are
65 building. Mining social networks can give some great insights about human nature [4, 29, 44];
66 who we really are, however, is even more accurately determined by where we spend our time
67 and which things we buy, rather than just what we say we do [28].

68 The process of analyzing the patterns within these digital breadcrumbs is called reality
69 mining [14, 33], and through it we can learn an enormous amount about who we are. The
70 Human Dynamics research group at MIT found that we can use them to tell if we are likely
71 to get diabetes [34], or whether we are the sort of person who will pay back loans [36]. By
72 analyzing these patterns across many people, we are discovering that we can begin to explain
73 many things — crashes, revolutions, bubbles — that previously appeared to be random acts of
74 God [31]. For this reason, the magazine Technology Review named our development of reality
75 mining as one of the ten technologies that will change the world [18].

2 The New Deal on Data

The digital breadcrumbs we leave behind provide clues about who we are, what we do and what we want. This makes personal data — data about individuals — immensely valuable, both for public good and for private companies. As European Consumer Commissioner, Meglena Kuneva said recently, “Personal data is the new oil of the Internet and the new currency of the digital world” [24]. This new ability to see the details of every interaction can be used for good or for ill. Therefore, maintaining protection of personal privacy and freedom is critical to our future success as a society. We need to enable even more data sharing for the public good; at the same time, we need to do a much better job in protecting the privacy of the individuals.

A successful data-driven society must be able to guarantee that our data will not be abused; perhaps especially that government will not abuse the power conferred by access to such fine-grain data. The abuses may be directly targeted at users, for example by offering them higher insurance rates based on their shopping history [17], or create problems for the entire society in the long run, for example by limiting user choices and closing them into information bubbles [20]. To achieve the positive possibilities of the new society, we require the *New Deal on Data*, workable guarantees that the data needed for public good are readily available while at the same time protecting the citizenry [33].

The key insight that motivates the idea of the New Deal on Data is that our data are worth more when shared, because these aggregated data — averaged, combined across population, and often distilled to high-level features — inform improvements in systems such as public health, transportation, and government. For instance, we have demonstrated that data about the way we behave and where we go can be used to minimize the spread of infectious disease [27,34]. Our research has reported how we were able to use these digital breadcrumbs to track the spread of influenza from person to person on an individual level. And if we can see it, we can stop it.

Similarly, if we are worried about global warming, these shared, aggregated data can show us how patterns of mobility relate to productivity [32]. In turn, this provides us with the ability to design cities that are more productive and, at the same time, more energy efficient. But in order

103 to obtain these results and make a greener world, we need to be able to see the people moving
104 around; this depends on many people willing to contribute their data, even if only anonymously
105 and in aggregate.

106 To enable sharing of personal data and experiences, we need secure technology and regulation
107 that allow individuals to safely and conveniently share personal information with each other,
108 with corporations, and with government. Consequently, the heart of the New Deal on Data
109 must be to provide both regulatory standards and financial incentives that entice owners to
110 share data, while at the same time serving the interests of both individuals and society at large.
111 We must promote greater idea flow among individuals, not just corporations or government
112 departments.

113 Unfortunately, today most personal data are siloed off in private companies and therefore
114 largely unavailable. Private organizations collect the vast majority of the personal data in the
115 form of mobility patterns, financial transactions, phone and Internet communications. These
116 data must not remain the exclusive domain of private companies, because then they are less
117 likely to contribute to the common good. Thus these private organizations must be the key
118 players in the New Deal on Data framework for privacy and data control. Likewise, these data
119 should not become the exclusive domain of the government, as this will not serve the public
120 interest of transparency; we should be suspicious of trusting the government with such power.
121 The entities who should be empowered to share and make decisions about their data, are the
122 people themselves: users, participants, citizens.

123 Through the years, the great goal of human societies was to find the efficient ways of gov-
124 ernance. The Big Data transformation can contribute to this ultimate goal of providing the
125 society with tools to analyze and understand what needs to be done, and to reach the consensus
126 on how to do it. This goes beyond simple creation of more communication platforms; the as-
127 sumption that more interactions between users will result in better decisions being made, may
128 be very misleading. Although in the recent years we have seen some great examples of using
129 social networks for better organization in society, for example during political protests [6, 19], we

are not even close to the point where we can start reaching consensus about the big problems: epidemics, climate change, pollution. We can improve the discussions by making them data driven, involving both experts and wisdom of the crowds – users themselves interested in improving the society. The problems we are dealing with as a now global society are more difficult than ever. We are responsible for many of them, and being able to tackle them on a global scale is necessary for our survival as a people.

3 Personal Data: Emergence of a New Asset Class

It has long been recognized that the first step to promoting liquidity in land and commodity markets is to guarantee ownership rights so that people can safely buy and sell. Similarly, the first step toward creating more new ideas and greater flow ideas (idea liquidity) is to define ownership rights. The only politically viable course is to give individual citizens key rights over data that are about them and in fact, these types of rights have undergirded the European Union’s Privacy Directive since 1995 [13].

We need to recognize personal data as a valuable asset of the individual that is given to companies and government in return for services. The simplest approach to defining what it means to own your own data is to draw an analogy with the English common law on ownership rights of possession, use, and disposal:

- You have the right to possess data about you. Regardless of what entity collects the data, the data belong to you, and you can access your data at any time. Data collectors thus play a role akin to a bank, managing the data on behalf of their customers.
- You have the right to full control over the use of your data. The terms of use must be opt-in and clearly explained in plain language. If you are not happy with the way a company uses your data, you can remove the data, just as you would close your account with a bank that is not providing satisfactory service.

- You have the right to dispose of or distribute your data. You have the option to have data about you destroyed or redeployed elsewhere.

Individual rights to personal data must be balanced with the need of corporations and governments to use certain data-account activity, billing information, and so on-to run their day-to-day operations. This New Deal on Data therefore gives individuals the right to possess, control, and dispose of copies of these required operational data, along with copies of the incidental data collected about you such as location and similar context.

Note that these ownership rights are not exactly the same as literal ownership under modern law, but the practical effect is that disputes are resolved in a different, simpler manner than would be the case for land ownership disputes, for example.

In 2007, one author (Pentland) first proposed the New Deal on Data to the World Economic Forum [45]. Since then, this idea has run through various discussions and eventually helped shape the 2012 Consumer Data Bill of Rights in the United States, along with a matching declaration on Personal Data Rights in the EU. These new regulations hope to accomplish the combined trick of breaking data out of the current silos, thus enabling the public good, while at the same time giving individuals greater control over data about them. But, of course this is still a work in progress and the battle for individual control of personal data rages onward.

The World Economic Forum (WEF) has dubbed personal data as the “New Oil” or resource of the 21st century [45]. The discovery of oil and the subsequent development of the oil industry over the past 100 years has spurred not only the development of the automobile industry but also the creation of the global transportation infrastructure, including the massive freeway networks that we see today in the developed nations. The “personal data sector” of the economy today is still in its infancy, its state akin to the oil industry at the late 1890s prior to the development of the Model-T Ford automobile. The productive collaboration between the Government (building the state owned freeways), the private sector (mining and refining oil, building automobiles), and the citizen (the user-base of these services) allowed the developed nations to expand their economies by creating new markets adjacent to the automobile and oil industries.

181 If personal data, as the new oil, is to reach its global economic potential, there needs to be
 182 a productive collaboration between all the stakeholders in the establishment of a *personal data*
 183 *ecosystem*. As mentioned in [45], a number of fundamental questions about privacy, property,
 184 global governance, human rights — essentially around who should benefit from the products
 185 and services built upon personal data — are major uncertainties shaping the opportunity. The
 186 rapid rate of technological change and commercialization in using personal data is undermining
 187 end user confidence and trust.

188 The current personal data ecosystem is fragmented and inefficient. Too much leverage is
 189 currently being accorded to service providers that enroll and register end-users. These siloed
 190 repositories of personal data exemplify the fragmentation of the ecosystem. These repositories
 191 contain data of varying qualities. Some are attributes of persons that are unverified, while
 192 other represent higher quality data that have been cross-correlated with other data points of the
 193 end-user.

194 For many participants, the risks and liabilities exceed the economic returns. Besides not
 195 having the infrastructure and tools to manage personal data, many end-users simply do not see
 196 the benefit of fully participating in the ecosystem. The current focus of many Internet-based
 197 service providers is to capture as much personal data from the end-user and to sell this data
 198 into the advertising industry. Personal privacy concerns are thus inadequately addressed at
 199 best, or simply overlooked in the majority of cases. The current technologies and laws fall short
 200 of providing the legal and technical infrastructure needed to support a well-functioning digital
 201 economy.

202 Recently, we have shown how challenging, but also feasible, it is to open such institu-
 203 tional Big Data. In the Data For Development (D4D) Challenge <http://www.d4d.orange.com>,
 204 the telecommunication operator Orange opened access to a large dataset of call detail records
 205 (CDRs) from the Ivory Coast. Working with the data as part of a challenge, teams of researchers
 206 came up with life-changing insights for the country. For example, one team developed a model
 207 for how disease spread in the country and demonstrated that information campaigns based on

one-to-one phone conversations among members of social groups can be an effective counter-measure [26]. In releasing and analyzing this data, the privacy of the people who generated the data was protected not only by technical means, such as removal of Personally Identifiable Information (PIIs), but also by legal means, with the researchers signing an agreement they will not use the data for re-identification or other nefarious purposes. As we have seen in several cases, such as the Netflix Prize privacy disaster [30] and other similar privacy breaches [39], true anonymization is extremely hard. In the Unique in the Crowd [10], de Montjoye et al. showed that even though human beings are highly predictable [37], we are also very unique. Having access to one dataset may be enough to uniquely fingerprint someone based on just a few datapoints, and use this fingerprint to discover their true identity.

The report of the World Economic Forum [45] also suggest a way forward by recommending a number of areas where efforts could be directed:

- Alignment of key stakeholders: Citizens, the private sector and the public sector need to work in support of one another. Efforts such as NSTIC [40] — albeit still in its infancy — represent a promising direction for a global collaboration.
- Viewing “data as money”: There needs to be a new change in mindset where an individual’s personal data items are viewed and treated in the same way as their money. These personal data items would reside in an “account” (like a bank account) where it would be controlled, managed, exchanged and accounted for just like personal banking services operate today.
- End-user centricity: All entities in the ecosystem need to recognize that end-users are vital and independent stakeholders in the co-creation and value exchange of services and experiences. Efforts such as the *User Managed Access* (UMA) initiative [2] point in the right direction by designing systems that are user-centric and managed by the user.

Opening data from the silos by publishing static datasets — collected at some point and unchanging — is important, but it is only the first step. We can do even more substantial things when the data is available in real time and can become part of a society’s nervous system.

234 Epidemics can be monitored and prevented in real time [34], underperforming students can be
235 helped, and people with health risks can be treated before they get sick [9].

236 4 Enforcing the New Deal on Data

237 How can we enforce this New Deal? The threat of legal action alone is important, but insufficient,
238 because if you cannot see abuses then you cannot prosecute them. Moreover, who wants more
239 lawsuits anyway? Enforcement can be addressed in significant ways without prosecution of public
240 statute or regulation at all. In many fields, companies and governments rely upon multi-party
241 frameworks of agreed upon rules governing common business, legal, and technical practices to
242 create effective self-organization and enforcement. These approaches hold promise as a method
243 for using institutional controls to form a reliable operational framework balancing the needs for
244 Big Data, privacy, and access.

245 One current best practice is a system of data sharing called trust networks. Trust networks
246 are a combination of networked computers and legal rules defining and governing expectations
247 regarding data. With respect to data belonging to individuals, these networks of technical and
248 legal rules keeps track of user permissions for each piece of personal data, and a legal contract
249 that specifies both what you can and cannot do with the data and what happens if there is a
250 violation of the permissions. For example, in such a system all personal data can have attached
251 labels specifying what the data can and cannot be used for. These labels are exactly matched
252 by the network's system rules and terms in legal contracts between all the participants, stating
253 penalties for not obeying the permission labels. These rules can, and often do, reference or
254 require audits of relevant systems and data use, demonstrating how traditional internal controls
255 can be leveraged as part of the transition to more novel trust models.

256 Complete tracking and regulation of every aspect of a trust network is not the goal or
257 even desirable in order to achieve effective enforcement. Rather, the rules for a trust network
258 align enforcement with the highest priority issues and those upon which trust of participants is
259 premised. The relevant issues for a given trust network arise from that systems underlying trust

models and the contextual scenarios within which the networked data and the relationships of parties occur.

When a trust network involves use of personal data, then the user permissions and corresponding limits on use are fundamental to the trust model. In this context, the permissions, including the provenance of the data, should require appropriate levels of audit. A well designed trust network, elegantly integrating computer and legal rules, allows automatic auditing of data use and allows individuals to change their permissions and withdraw data.

Having system rules applicable to the networks, applications, and data as well as all the services providers, other intermediaries, and the users themselves is the mechanism for establishing and operating a trust network. System rules are sometimes called operating regulations in the credit card context or known as trust frameworks in the identity federations context or trading partner agreements in a supply value chain context. There are many general examples of multi-party shared architectural and contractual rules that share the generic characteristic of creating binding obligations and enforceable expectations on all participants in scalable networks. Another common characteristic of the system rules design pattern is that the participants in the network can be widely distributed across very heterogeneous business ownership boundaries, legal governance structures, and technical security domains. Yet, the parties need not agree to conform to all or most aspects of their basic roles, relationships, and activities in order to connect to systems of a trust network. Cross-domain trusted systems must, by their nature, focus mandatory and enforceable rules narrowly upon the critical items that must be commonly agreed in order for that network to achieve its purpose.

For example, institutions participating in credit card and automated clearing house debit transactional networks are subject to profoundly different sets of regulations, business practices, economic conditions, and social expectations. The network rules focus upon the topmost agreed items affecting interoperability, reciprocity, risk, and revenue allocation. The knowledge that fundamental rules are subject to enforcement actions is one of the foundations of trust as well as a motivation to prevent or address violations before they trigger penalties. A clear example

287 of this approach can be found with the Visa Operating Rules, covering a vast global real-time
288 network of parties that agree to rules governing their roles in the system as merchants, banks,
289 transaction processors, individual or business card holders, and other key system roles.

290 A system like this has made the interbank money transfer system among the safest systems
291 in the world and the daily backbone for exchanges of trillions of dollars, but until recently such
292 systems were only for the ‘big guys’. To give individuals a similarly safe method of managing
293 personal data, the Human Dynamics research group at MIT, in partnership with the Insti-
294 tute for Data Driven Design, co-founded by John Clippinger and one author (Pentland), have
295 helped build open Personal Data Store (openPDS) [11]. See <http://openPDS.media.mit.edu>
296 for project information and <https://github.com/HumanDynamics/openPDS> for the open source
297 code.

298 The openPDS is a consumer version of a personal cloud trust network that we are now
299 testing with a variety of industry and government partners. Soon, sharing your personal data
300 could become as safe and secure as transferring money between banks.

301 The Human Dynamics Lab has applied the system rules approach to development of in-
302 tegrated business, technical architecture, and rules large scale institutional use of personal
303 data stores, available as an example under MIT’s creative commons license by MIT, at [https:](https://github.com/HumanDynamics/SystemRules)
304 [//github.com/HumanDynamics/SystemRules](https://github.com/HumanDynamics/SystemRules).

305 When it comes to data intended to be accessible over networks — whether big, personal, or
306 otherwise — the traditional container of an institution makes less and less sense. Institutional
307 controls apply, by definition by or to some type of institutional entity such as a business, gov-
308 ernmental, or religious organization. A combined view of the business, legal, and technical facts
309 and circumstances surrounding Big Data is necessary to know what access, confidentiality, and
310 other expectations exist. The relevant contextual aspects of Big Data of one institution is often
311 profoundly different from that of another. As more and more organizations use and rely upon
312 Big Data, a single formula for institutional controls will not work for increasingly heterogeneous
313 business, legal, and technical environments in play. Many organizations are structured with clear

314 leadership on business, legal, and technical issues functionally assigned to top level executive
 315 roles. Business issues are typically allocated to roles such as CEO, COO, or CFO, while leader-
 316 ship on legal issues is commonly assigned to roles like general counsel and regulatory compliance
 317 and technical leads are often the roles of CIO, CTO, or CSO. Having top level leadership for
 318 each of the business, legal, and technical aspects of a trust network is a critical success factor.

319 The capacity to apply the appropriate methods of enforcement for a trust network depend
 320 upon a clear understanding and agreement among parties about the purpose of the trusted
 321 system and the respective roles or expectations of those connecting as participants. Therefore,
 322 an anchor is needed to a clear context of a Big Data operational framework and institutional
 323 controls appropriate for access and confidentiality or privacy. The following section posits the
 324 trust model and signature traits of such a context, through the lens of the New Deal on Data.

325 5 Transitioning End-User Assent Practices

326 The way users grant authorizations to their data is not a trivial matter. The flow of personal
 327 information, such as location data, purchases and health records can be very complex. Every
 328 tweet, geo-tagged picture, phone call, or purchase with credit card, provide the user's location
 329 not only to the primary service, but also to all the applications and services that have been
 330 authorized to access and reuse these data. The authorizations may come from the end-user
 331 or be granted by the collecting service, based on an umbrella terms of service, allowing the
 332 re-use of the data. Implementation of such flows was a crucial part of the Web 2.0 revolution,
 333 realized with RESTful APIs, mashups, and authorization-based access. The way the personal
 334 data travel between the services has however become arguably too complex for a user to handle
 335 and manage.

336 Increasing the amount of data controlled by the user and granularity of this control is mean-
 337 ingless if it cannot be exercised in an informed way. For many years, the End User License
 338 Agreements (EULAs), long incomprehensible texts have been accepted blindly by the user,
 339 trusting they have not agreed to anything that could harm them. The process of granting the

authorizations cannot be too complex, as it would prevent the user from understanding her decisions. At the same time, it cannot be too simplistic, as it may not sufficiently convey the weight of the privacy-related decisions. It is a challenge in itself, to build the end-user assent systems that allow the user to understand and adjust their privacy settings. Complex EULAs do not promote the privacy of the users, effectively pushing them to press *I Agree* in every presented window.

This gap between the interface — single click — and the effect, can render the data ownership meaningless; the click may wrench people and their data into systems and rules that are antithetical to fair information practices, such as is prevalent with today’s end-user licenses in cloud services or applications. Managing the potentially long term and opposite dynamics fueled by old deal systems operating simultaneously with the new deal systems is an important design and migration challenge during the transition to a Big Data economy. During this transition and after the New Deal on Data is no longer new, personal data must continue to flow in order to be useful. Protecting the data of people outside of the user-controlled domain is very hard without a combination of cost effective and useful business practices, legal rules, and technical solutions.

We envision Living Informed Consent, where the user is entitled to know what data is being collected about her by which entities, empowered to understand the implications of data sharing, and finally put in charge of the sharing authorizations. We suggest the readers ask themselves a question: *Which services know which city I am in today?*. Google? Apple? Twitter? Amazon? Facebook? Flickr? This small application we have authorized a few years ago to access our Facebook check-ins and forgot since then? This is an example of a fundamental question related to user privacy and assent, and yet finding the answer to it may be surprisingly difficult in today’s ecosystem. We can hope that most of the services treat the data responsibly and according to user authorizations. In the complex network of data flows however, it is relatively easy for the data to leak to careless or malicious services [7]. We need to build the solutions to help the user to make well informed decisions about data sharing.

367 6 Big Data and Personal Data Institutional Controls

368 The phrase “institutional controls” refers to safeguards and protections by use of legal, policy,
 369 governance, and other non-strictly technical, engineering, or mechanical measures. The phrase
 370 institutional controls in a Big Data context can perhaps best be understood by examining how
 371 the concept has been applied to other domains. The most prevalent use of institutional controls
 372 has been in the field of environmental regulatory frameworks.

373 A good example of how this concept supports and reflects the goals and objectives of en-
 374 vironmental regulation can be found in the policy documents of the Environmental Protection
 375 Agency (EPA). This following definition is instructive, and is part of the Institutional Control
 376 Glossary of Terms [42]:

377 *Institutional Controls - Non-engineering measures intended to affect human activ-*
 378 *ities in such a way as to prevent or reduce exposure to hazardous substances. They*
 379 *are almost always used in conjunction with, or as a supplement to, other measures*
 380 *such as waste treatment or containment. There are four categories of institutional*
 381 *controls: governmental controls; proprietary controls; enforcement tools; and infor-*
 382 *mational devices.*

383 Going deeper, the article by DeMeo and Doar [12] defines institutional controls thusly:

384 *Institutional controls are administrative and legal controls that help minimize the*
 385 *potential for human exposure to contamination and/or protect the integrity of the*
 386 *physical remedy. They can include recorded restrictive covenants, but land use laws*
 387 *and regulations, deed restrictions, department consent orders, and conservation ease-*
 388 *ments are all institutional controls.*

389 In domains of information technology, this approach is most commonly reflected as “enter-
 390 prise controls” related to security. See, for example, the Juniper Networks enterprise security
 391 report [23] stating: “Enterprise mobility technologies, especially those designed to retrofit en-
 392 terprise controls on top of consumer mobile devices, are rapidly evolving. This was a message

we heard loud and clear in the study.” This study and analysis also reveals much about the internal controls needed to accommodate mobile device use by employees. In both capacities as employee, consumer, and other roles, the use of mobile devices triggers myriad legal, policy, and other implications for institutional controls.

In the legal domain, this concept frequently emerges under the moniker “regulatory compliance” or “legal compliance” anchored in legal and regulatory frameworks such as Health Insurance Portability and Accountability Act (HIPAA) and Sarbanes-Oxley (SOX). These statutory legal frameworks require covered organizations to establish integrated sets of governance, legal, transactional, security, and other internal controls to avoid violating the rules. The institutional controls are accomplished in tight integration with engineering and other measures in order to ensure compliance and to control legal and security risk. The use of institutional controls of this type are fundamental methods for achieving and maintaining the transition to a digital, networked, and Big Data footing for any private company, government agency, or other organization.

Consider again the analogy of institutional controls in the context of environmental law, and how these types of measures can be applied in the Big Data, privacy, and access context to digital environments. Given the relatively mature and stable state of environmental regulation, there is much to be learned by examining this context of institutional controls. Environmental regulatory compliance with waste management cleanup requirements could include institutional controls restricting land use on adjacent property. In these situations, it is possible that the remediation strategy requires significant use of land outside the property boundaries of the cleanup site. In these cases, the regulators and the land owner responsible for the regulated property must find ways to ensure a common approach among multiple owners and across multiple property environments. Clauses on the relevant deeds, an enforceable consent order, or targeted regulations and zoning rules are examples of more severe institutional controls that can be employed to ensure consistent and effective actions are taken across ownership and real property boundaries.

420 See, for example, Florida Department of Environmental Protection (FDEP), Division of
421 Waste Management [16] which states that “...RMO III does contemplate contamination beyond
422 the Property boundaries, which would require agreement by the adjacent owners to put an RC
423 on their properties as well.”

424 The concept of an “institutional control boundary” is especially clarifying and powerful when
425 applied to the networked and digital boundaries of an institution. In the context of Florida’s
426 environmental regulation frameworks, the phrase is applied to describe the various types of
427 combinations risk management levels related to target cleanup standards and extend beyond
428 the area of a physical property boundary. Also see a recent University of Florida report on
429 Development of Cleanup Target Levels (CTLs) [8] stating “Risk Management Options Level
430 III, like Level II, allows concentrations above the default groundwater CTLs to remain on site.
431 However, in some rare situations, the institutional control boundary at which default CTLs must
432 be met can extend beyond the site property boundary.”

433 The EPA provides considerable information on the nature and use of institutional controls,
434 including situations when the situational scope extends to adjacent properties owned by third
435 parties. See, generally, *EPA Hazardous Waste Corrective Action Guidance on Institutional Con-*
436 *trols* [42]. Also see: *Institutional Controls Bibliography: Institutional Control, Remedy Selection,*
437 *and Post-Construction Completion Guidance and Policy, December 2005* [41].

438 When institutional controls would apply to “separately owned neighboring properties” a
439 number of issues arise that are very relevant to the problems associated with managing personal
440 and big data across legal, business and other systemic boundaries. Requiring the party respon-
441 sible for site cleanup to use “best efforts” to attain agreement by third parties to institute the
442 relevant institutional controls is perhaps the most direct and least prescriptive approach. When
443 direct negotiated agreement is not successful, then use of third party neutrals to resolve disagree-
444 ments regarding institutional controls can be required. If necessary, environmental regulation
445 can force an acquisition of neighboring land by compelling the party responsible to purchase the
446 other property or by purchase of the property directly by the EPA [43].

447 In the context of Big Data, privacy, and access, institutional controls are seldom, if ever,
 448 the result of government regulatory frameworks such as are seen in the environmental waste
 449 management oversight by the EPA. Rather, institutions applying measures constituting institu-
 450 tional controls in the Big Data and related information technology and enterprise architecture
 451 contexts will typically employ governance safeguards, business practices, legal contracts, tech-
 452 nical security, reporting, and audit programs and various risk management measures.

453 Inevitably, institutional controls for Big Data will have to operate effectively across institu-
 454 tional boundaries, just as environmental waste management internal controls must sometimes
 455 be applied across real property boundaries and may subject multiple different owners to enforce-
 456 ment actions corresponding to the applicable controls. Short of government regulation, the use
 457 of system rules as a general model are one widely understood, accepted, and efficient method
 458 for defining, agreeing, and enforcing institutional and other controls across business, legal, and
 459 technical domains of ownership, governance, and operation.

460 The use of system rules and integrated participation agreements by developers and end-
 461 users is a way to ensure intended operational frameworks conform to applicable institutional
 462 controls. The example of Living Informed Consent described in this chapter, demonstrates how
 463 institutional controls comprised of legal and definite workflow measures, in concert with technical
 464 methods, can result in a higher level of performance, while appropriately balancing legitimate
 465 interests of various parties regarding use and access to personal data.

466 Following the World Economic Forum recommendations of treating personal data stores in
 467 the manner of bank accounts [45], there are a number of infrastructure improvements that need to
 468 be realized, if the personal data ecosystem is to flourish and deliver new economic opportunities.
 469 We believe the following infrastructure improvements are necessary for the coming personal data
 470 ecosystem:

- 471 • *New global data provenance network*: In order for personal data to be treated like bank
 472 accounts, the origin information regarding data items coming into the data store must be
 473 maintained [22]. In other words, the provenance of all data items must be accounted for

by the IT infrastructure upon which the personal data store operates. The heterogeneous provenance databases must then be interconnected in order to provide a resilient and scalable platform for audit and accounting systems to track and reconcile the movement of personal data from the respective data stores.

- *Trust network for computational law:* In order for trust to be established between parties who wish to exchange personal data, we foresee that some degree of “computational law” technologies may have to be integrated into the design of personal data systems. Such technologies should not only verify terms of contracts (e.g. terms of data use) against user-defined policies but also have mechanisms built-in to ensure non-repudiation of entities who have accepted these digital contracts. Efforts such as [1, 2] are beginning to bring better evidentiary proof and enforceability of contracts into the technical protocol flows.
- *Development of institutional controls for digital institutions:* Currently there are a number of proposals for the creation of virtual currencies (e.g. BitCoin [5], Ven [38]) in which the systems have the potential to evolve into self-governing “digital institutions” [21]. Such systems and institutions that operate on them will necessitate the development of a new paradigm to understand the aspects of institutional control within their context.

7 Scenarios of Use in Context

Development of frameworks for Big Data that effectively balance economic, legal, security and other interests requires an understanding of the relevant context and applicable scenarios within which the Big Data exists. Although Big Data straddles multiple business, legal, and technical boundaries it will nonetheless have one or more institutions that are capable of, or in some situations required to, manage and control it. The public good referred to in the title of this book can be articulated through the use of system, service and software modeling, requirements setting, development, testing and certification processes. Discrete use cases of actors and actions is one approach to model business, legal and technical requirements in a way that can objectively

499 be agreed in advance and traceably be tested against implemented systems and components.
500 However, user cases are typically atomic or very low level of granularity and operate deep within
501 layers of assumed context. Higher level contexts and corresponding scenarios of multiple use
502 cases can describe fundamental expectations about matters like interests in property, rights to
503 liberty and honoring the social compact.

504 Consider that the applicable scenario within which the data exists can provide a method and
505 mechanisms of sorts to establish the basic ownership, control and other expectations of the key
506 parties. For example, it may not be sufficient to describe the exchange of money and financial
507 information because the nature of the transaction and their respective data and systems are not
508 identified enough to predict the rights and obligations or other outcomes reasonably expected
509 by individuals and organizations that engage in the activity of a financial exchange. The sale of
510 used cars via an app, the conduct of a counseling session via Google Hangout and the earning
511 of a masters degree via an online university all represent scenarios wherein the use case of
512 a financial exchange takes place. However, each of these scenarios occurs in contexts that are
513 easily identifiable, involving the sale of goods and deeper access to financial information if the car
514 is financed, or involving the practice of therapy by a licensed professional involving confidential
515 mental health data or involving elearning services and protected educational records and possibly
516 deeper financial information if the program is funded by scholarship or loans. Identifying the
517 people (a consumer and a used car dealer) the transaction (purchase of a used car) the data
518 (sales and title data, finance information, etc) and the systems (the third party app and it's
519 relevant services or functions, state DMV services, credit card and bank services, etc) provide
520 enough context to establish generally what existing consumer rights under the relevant state
521 lemon laws, the Uniform Commercial Code and other applicable rules will govern when duties
522 arise or are terminated, what must be promised, what can be repudiated, by whom data must
523 be kept secure and other requirements or constraints on the use of personal data and Big Data.
524 These and other factors vary when a transaction that is otherwise identical seeming operates
525 within different scenarios, and even scenarios will differ depending upon which contexts apply.

526 The basic common law inspired ownership tenants of the New Deal on Data are general
527 principles that guide and inform basic relationships and expectations. However, the dynamic
528 bundle of recombinant rights and responsibilities constituting "ownership" interests in personal
529 data and expectations pertaining to Big Data vary significantly from context to context and
530 even from one scenario to another within a given general context. Institutional controls and
531 other system requirements or safeguards are important methods to ensure context-appropriate
532 outcomes consistent with clearly applicable system scenarios that set the contours and under-
533 pinnings for a greater public good. The New Deal on Data can be achieved in part by sets of
534 institutional controls involving governance, business, legal, and technical aspects of Big Data
535 and interoperating systems. Reference to relevant scenarios reveal signature features of the New
536 Deal on Data in various contexts and can serve as an anchor to evaluate what institutional
537 controls are well aligned to achieve a balance of economic, privacy and other interests.

538 The types of requirements and rules governing participation by individuals and organizations
539 in Trust Networks vary depending on the facts and circumstances related to the transactions,
540 data types, relevant roles of people and other factors. Antecedent but relevant networks such
541 as credit card systems, trading partner systems and exchange networks are instructive not only
542 for their many common elements but also as important examples of how vastly different they
543 are from one another depending upon contexts, scenarios, legal obligations, business models,
544 technical processes and other signature patterns. Trust Networks that are formed to help manage
545 Big Data in ways that appropriately respect personal data rights and other broader interests
546 similarly will succeed to the extent they can tolerate or promote a wide degree of heterogeneity
547 among participants for those business, legal and technical matters that need not be uniform
548 or directly harmonized. In some situations, new business models and contexts will emerge that
549 require fresh thinking and novel combinations of roles or types of relationships among transacting
550 parties. In these cases, understanding the actual context and scenarios will serve as a critical
551 anchor for establishment of acceptable and sustainable business, legal and technical rules and
552 systems.

Which scenarios are relevant and what lower level use cases apply are knowable in detail only with reference to the relevant context of a factually based situation. Relevant scenario of use are comprised of people conducting transactions through systems in which personal data and Big Data exists or flows. It is possible to test whether frameworks for engagement successfully address Big Data, privacy and the public good by testing outcomes of relevant scenarios. Scenarios are capable of adequately defining these high level goals and objectives when they identify each of the following four elements:

1. Who are the people in the scenario (e.g. who are the parties involved and what are their respective roles and relationships)?
2. What are the relevant interactions (e.g. what transactions or other actions are conducted by or with the people involved)?
3. What are the relevant data and data sets (e.g. what types of data are created, stored, computed, transmitted, modified or deleted)?
4. What are the relevant systems (e.g. what services or other software is used by the people, for the transactions or with the data)?

Retail marketing is a common context within which personal data is important. Personal data is critical to many different scenarios in the context of retail marketing. Consider the scenario whereby a merchant conducts an online promotion for an app or service by using a purchased direct marketing database of consumers who have expressed interest in similar products. Data such as the names, email addresses, phone numbers and other personal information can be used to lower costs and increase revenue by better targeting promotional messages and increasing sales. However, there are risks to the merchant and consumer alike, including the potential of a data breach and resulting identity theft and fraud. There is also risk that some consumers will feel annoyed or violated when their personal information is used in this manner without their prior knowledge or consent. The information available from such third party

578 marketing lists and databases may be out of data and lead to the wast of marketing dollars and
579 the failure to inform potentially interested consumers of a product they might have purchased if
580 the solicitation had gone to their current email or appropriate network. Imagine that the same
581 consumers had individual personal data stores and were able to "intent-cast" their interest in
582 the product. This can be done without revealing all the other personal data of that person. The
583 The openPDS system could be configured to provide permission based answers to questions such
584 as whether the consumer is over the age of 18 or lives in a city, suburb or rural area. Sectors
585 such as real estate could be transformed by such intent-casting by qualified buyers.

586 Another common context involving personal data is governmental transactions with the
587 public. Government filings, registrations, permits and other such public sector transactions with
588 the individuals or organizations create a large volume and variety of personal data flow. Consider
589 the scenario whereby a person runs a small business and must comply with tax, employee
590 related, licensing and other rules by filing forms with multiple government agencies at the federal,
591 state and local levels. Individuals names, addresses, occupations, dates of birth, social security
592 numbers and many other types of personal information are common elements of such filings.
593 Similarly to the retail marketing scenario above, the parties to government filing transactions
594 also risk unauthorized access to the personal data by interception during transmission or by
595 breach of data storage systems. In addition, the costs associated with requiring the same data
596 by many different agencies and updating or correcting data are born by both the filer and the
597 regulator. What if the people who own or operate such businesses had access to the services
598 and functions of a personal data store for themselves individually and also for the corporate
599 entity they operated? Routine changes in status, such as a change of address or name, could
600 be accomplished in a secure manner once via their own data service and leveraged again and
601 again by the many faces of government requiring that data. When the authoritative source
602 of such information can be deemed to be housed within or logically connected to a person's
603 data store, then the laborious task of address verification and tedious forms and other processes
604 required by each government entity could be avoided. The saving of direct and indirect costs,

the regaining of time spent by each agency and business and avoidance of delays and uncertainty are of significant value to all parties (See: <http://kansasbusinesscenter.com> and see the data files at <https://github.com/kansasbusinesscenter>)

The scenario below describes deeper fact-based situations and circumstances in the context of social science research and studies involving personal data and Big Data. Note how the roles of people, their interactions, the use of data and the design of the corresponding systems reflect and support the New Deal on Data in ways that deliberately provide immediate and increasing value to the stakeholders than is typical or expected typically.

7.1 Example Scenario: Research System for Computational Social Science

In order to achieve low-risk high-value research outcomes efficiently, design and deployment of the coming global wave of Big Data systems should apply relevant research, such as that identified in this chapter and the book generally.

Computational Social Science (CSS) studies are based on data collected often with an extremely high resolution and scale [25]. Using computational power combined with mathematical models, such data can be used to provide insights into human nature. Much of the data collected, for example mobility traces are sensitive and private; most individuals would feel uncomfortable sharing them publicly.

The data collection in the CSS context is based on the informed consent of the participants. Countries have different bodies regulating such studies, for example Institutional Research Boards (IRBs) in the US. Although certain minimal requirements for implementing informed consent in these contexts exist [35], they are often not very well suited for the large-scale studies, where the amount and sensitivity of the data calls for sophisticated privacy controls. As the scale of the studies grows, in terms of the number of participants, collected bits per user, and duration, the EULA-style informed consent is no longer sufficient and makes it hard to claim that participants in fact expressed informed consent.

One author (Stopczynski) has recently deployed a 1,000 phones study at Technical University

631 of Denmark, where freshmen students received mobile phones in order to study their networks
632 and social behavior in the important change moment of their lives, when joining the university.
633 The study, called SensibleDTU (<https://www.sensible.dtu.dk/?lang=en>), uses not only data
634 collected from the mobile phones (location, Bluetooth-based proximity, call and sms logs etc.)
635 but also data collected from social networks, questionnaires filled out by participants, behavior
636 in economic games and so on. As the data is collected in the context of the university, there is
637 potentially a big issue of students feeling obliged to participate in the study or that the data may
638 influence their grades. In this context, we see the implementation of Living Informed Consent
639 not only as a technical mean to put participants in control of the data we collect, but also
640 to clearly and comprehensibly convey broader New Deal on Data principles such as the opt-in
641 nature of the study, the boundaries of the data usage, and parties accessing the data.

642 As the study will last for several years, hopefully allowing us to see the life of a student from
643 the very first friendships made until the graduation party, the consent must remain alive. It is
644 again a matter of balance: we do not want the participants to feel under constant surveillance —
645 data is used mostly in aggregated form — at the same time to remember that in fact, the data
646 is being collected and used. We are still trying to understand how to achieve this equilibrium:
647 how often should we remind the users about the collection effort? Should they re-authorize
648 applications from time to time? We see a great hope in the applications we create for the users
649 to provide certain services, simple such as life-logging where they can see how active they are,
650 what are their top places etc. and more advanced, such as artistic visualizations of their social
651 networks. Making the user aware of the data by transforming them into value, can greatly
652 benefit the privacy, making users constantly aware what is being collected, but also what kind
653 of value they can get out of it.

654 It is important for science and research to develop further solutions and options ensuring
655 contextually appropriate rules can be applied by Big Data systems. For rules to be effectively
656 applied, systems must not only be able to establish which rules apply but also support the right
657 functional capabilities and have appropriate information structure, format, and meta-data.

Big Data, by its nature, represents a new set of business, legal, and technical capabilities and requirements. The key observation is that virtually all Big Data systems have yet to be designed, implemented, customized, or deployed. Institutions that are the current early adopters of today's Big Data system will soon replace those systems and the rest of the world will adopt Big Data systems in phases over time. Based upon this observation, it follows that design improvements made now or soon will have much greater impact than can be had after mass-scale adoption has occurred.

7.2 Scenarios of Use Today, Tomorrow, and the Day After

The New Deal on Data is designed to provide good value to all stakeholders creating, using or benefiting from personal data, but the entire vision need not be adopted before value starts to flow. The mentioned social science research study scenario, demonstrates how researchers and study participants alike derive value from New Deal on Data principles today. As more researchers use the type of systems described above, the value is predicted to increase based upon a network effect. The same dynamic is expected in other contexts as well.

Adopting New Deal on Data principles on a large scale can be accomplished iteratively, such as one economic sector, transaction type or data type at a time. A reasonable success metric for adoption of large scale visions such as the New Deal on Data is whether change management has been designed to achieve enough value at every phase for every key stakeholder group to make the change worth the effort. Value to all parties participating in the New Deal on Data increases as direct or indirect use and re-use of personal data is available in greater volumes and varieties. Such volume and variety of personal data increases as more parties and transaction types and data sets and systems adopt and interoperate within the New Deal on Data.

By staging and phasing adoption of the New Deal on Data typical objections to change based on grounds of cost, disruption, or over regulation can be addressed. Policy incentives can further address these objections, such as allowing safe harbor protections for conduct of organizations operating under the rules of a trust network. Policy makers can resolve other difficulties by

684 combinations of strategic transition management methods like allowing safe harbor compliance
685 delays, or approving alternative adoption paths and granting other non-substantive waivers to
686 ease any burdens of migrating to new business methods.

687 Developing relevant context and scenarios defines a clear anchor for measuring whether a
688 given use of Big Data and personal data is consistent with measurable criteria. Such criteria
689 can be used to establish compliance with the rules of a Trust Network and for certification by
690 government for the right to safe harbor or other protections. Criteria applicable to business,
691 legal, and technical aspects of a system or set of systems can be assessed, evaluated, and trace-
692 ably proven. Such criteria can provide a basic lowest common denominator requirements and
693 constraints for work flow, transaction flow, data flow, and service flow within the relevant con-
694 texts and scenarios of use. The New Deal on Data provides a clear basis routed in common law
695 and broad understandings of the social compact. Therefore, with the New Deal on Data the
696 appropriate bundle of rights and expectations intended to cover privacy and other personal data
697 interests in Big Data can be explicitly enumerated, debated, and eventually agreed in ways that
698 fit relevant contexts.

699 We must move beyond the closed, laboratory-based question-and-answering process that we
700 currently use, and begin to manage our society in a new way. We must begin to test connections
701 in the real world far earlier and more frequently than we have ever had to do before, using the
702 methods the Human Dynamics research group have developed with our collaborators for the
703 Friends and Family [3] or the SensibleDTU (<https://www.sensible.dtu.dk>) study. We need
704 to construct Living Laboratories — communities willing to try a new way of doing things or, to
705 put it bluntly, to be guinea pigs — in order to test and prove our ideas. This is new territory
706 and so it is important for us to constantly try out new ideas in the real world in order to see
707 what works and what does not.

708 An example of such a Living Lab is the ‘open data city’ just launched by one author (Pent-
709 land) with the city of Trento in Italy, along with Telecom Italia, Telefonica, the research uni-
710 versity Fondazione Bruno Kessler, the Institute for Data Driven Design, and local companies.

711 Importantly, this Living Lab has the approval and informed consent of all its participants. Not
 712 only do these participants consent to sharing of their data, they know that they are part of a
 713 gigantic experiment whose goal is to invent a better way of living. This can be a model followed
 714 by many types of systems within and beyond the social science research contexts. More detail
 715 on this Living Lab can be found at <http://www.mobileterritoriallab.eu/>.

716 The goal of this Living Lab is to develop new ways of sharing data to promote greater civic
 717 engagement and exploration. One specific goal is to build upon and test trust-network software
 718 such as our openPDS system. Tools such as openPDS make it safe for individuals to share
 719 personal data (e.g., health data, facts about your children) by controlling where your data go
 720 and what is done with them.

721 The specific research questions we are exploring depend upon a set of “personal data ser-
 722 vices” designed to enable users to collect, store, manage, disclose, share, and use data about
 723 themselves. These data can be used for the personal self-empowerment of each member, or
 724 (when aggregated) for the improvement of the community through data commons that enable
 725 social network incentives. The ability to share data safely should enable better idea flow among
 726 individuals, companies, and government, and we want to see if these tools can in fact increase
 727 productivity and creative output at the scale of an entire city.

728 8 Conclusions

729 Our societies today face unprecedented challenges. Solving these problems will require access
 730 to personal data, so we can understand how the society works, how we move around, what
 731 makes us productive, and how everything from ideas to diseases spread. The insights must be
 732 actionable, available in real-time, and engaging the population, creating the nervous system of
 733 the society. In this chapter we have reviewed how Big Data collected in institutional context
 734 can be used for the public good. In many cases, the data needed for creating better society is
 735 already collected and exists closed in silos of companies and governments. Using well designed
 736 and implemented sets of institutional controls, covering business, legal, and technical dimensions,

we described how the silos can be opened. The framework for doing this — the New Deal on Data — postulates that the primary driver of the change must be by recognizing that ownership of personal data rests with the people about whom that data is about. This ownership, the right to use, transfer, and remove the data ensures that the data is available for public good, while at the same time protecting the privacy of the citizens.

The New Deal on Data is still new. Here we described our efforts in understanding the technical means of how it can be implemented, the legal framework around it, business ramifications, and the direct value that can be derived from researchers, companies, governments, and users having more access to the data. It is clear that companies must play the major role in the implementation of the New Deal, incentivized by business opportunities and pressured by the legislation and demand of the users. Only with such orchestration will it be possible to change the current feudal system of data ownership and finally put the immense quantities and capabilities of collected personal data to good use.
